

Assignment-4: DBMS

Topics: Relational Algebra, ER Models, FDs, and Normalization

1. Basic Operations of Relational Algebra

Relational Algebra provides a set of operations to manipulate relations (tables) in a database.

Operation	Description	Example
SELECT (σ)	Filters rows based on a condition.	$\sigma_{\text{Dept} = \text{'CSE'}}(\text{STUDENT})$ — selects all CSE students.
PROJECT (π)	Selects specific columns.	$\pi_{\text{Name}, \text{Dept}}(\text{STUDENT})$ — shows only Name and Dept columns.
UNION (\cup)	Combines tuples from two relations.	$\text{STUDENT1} \cup \text{STUDENT2}$
SET DIFFERENCE ($-$)	Shows tuples in one relation but not in the other.	$\text{STUDENT} - \text{ALUMNI}$
CARTESIAN PRODUCT (\times)	Combines every tuple of one relation with another.	$\text{STUDENT} \times \text{DEPARTMENT}$
RENAME (ρ)	Renames relation or attributes.	$\rho_{\text{S}}(\text{STUDENT})$ — renames STUDENT as S
JOIN (\bowtie)	Combines related tuples using common attributes.	$\text{STUDENT} \bowtie_{\text{STUDENT.DeptID} = \text{DEPARTMENT.DeptID}} \text{DEPARTMENT}$

2. Relational Algebra Expressions

Relations:

```
STUDENT(RollNo, Name, DeptID)
DEPARTMENT(DeptID, DeptName)
```

(a) Students in 'CSE' department:

$$\pi \text{Name}(\sigma \text{DeptName} = 'CSE'(\text{STUDENT} \bowtie \text{STUDENT.DeptID} = \text{DEPARTMENT.DeptID} \text{ DEPARTMENT}))$$

(b) Departments with no students:

$$\pi \text{DeptName}(\text{DEPARTMENT}) - \pi \text{DeptName}(\text{STUDENT} \bowtie \text{DEPARTMENT})$$

3. ER Diagram for Online Shopping System

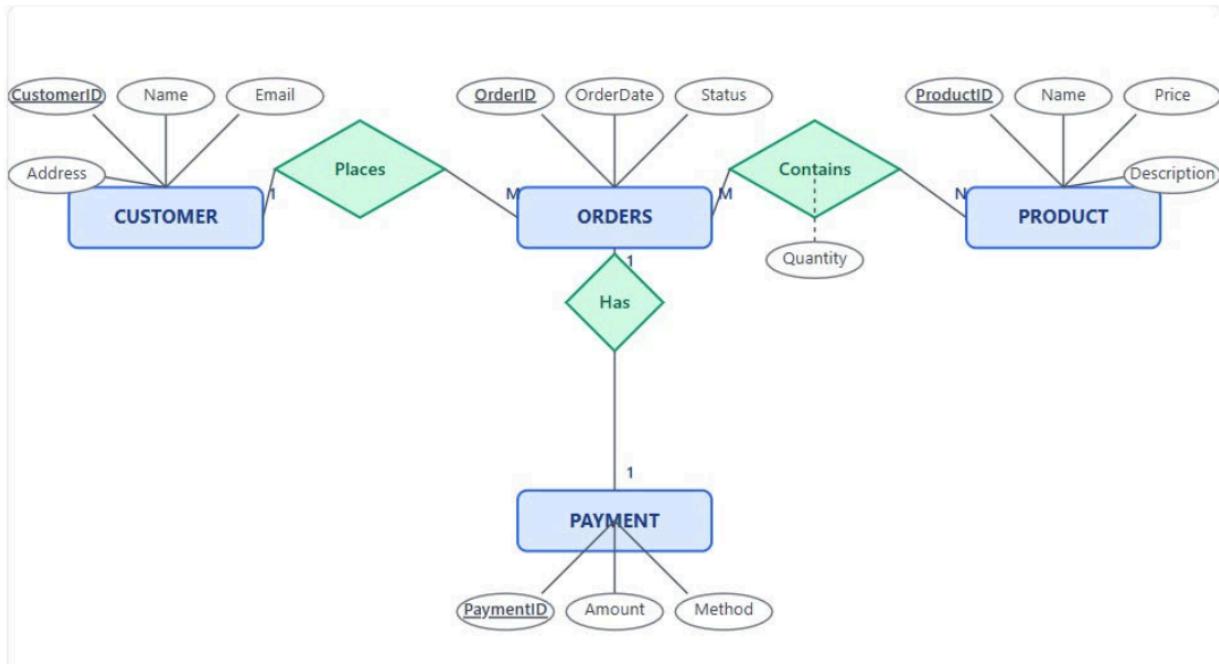

Entities:

- **Customer**(CustomerID, Name, Email, Phone)
- **Product**(ProductID, ProductName, Price, StockQty)
- **Order**(OrderID, OrderDate, CustomerID)
- **Payment**(PaymentID, OrderID, Amount, Date, Mode)

Relationships:

- Customer places Order → *One-to-Many*
- Order contains Product → *Many-to-Many* (Resolved using OrderDetails)
- Order makes Payment → *One-to-One*

ER Model:

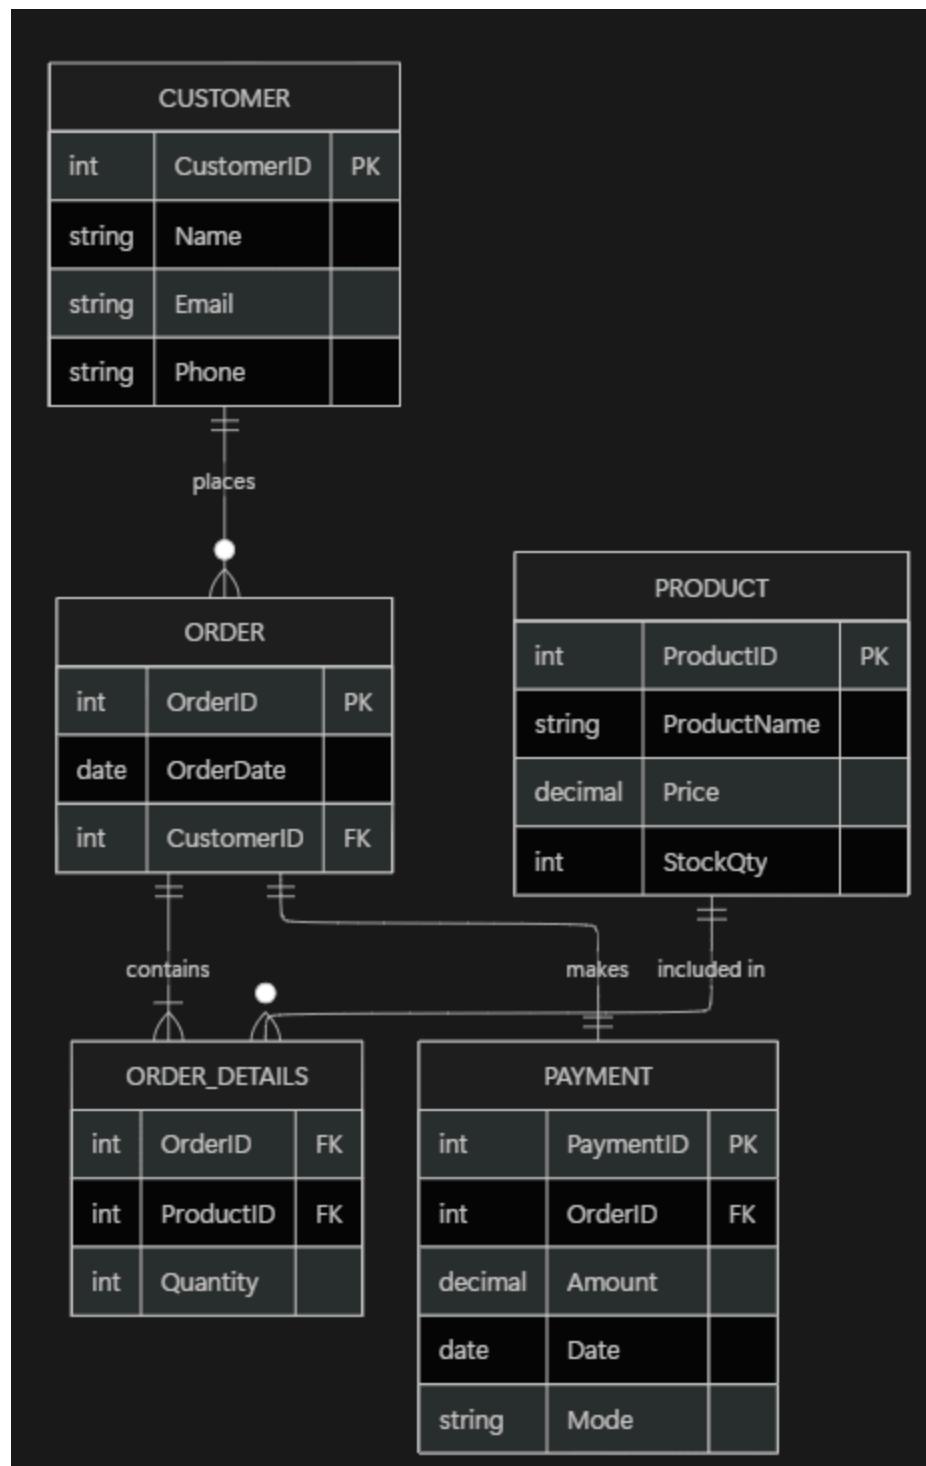

Relational Schema:

```

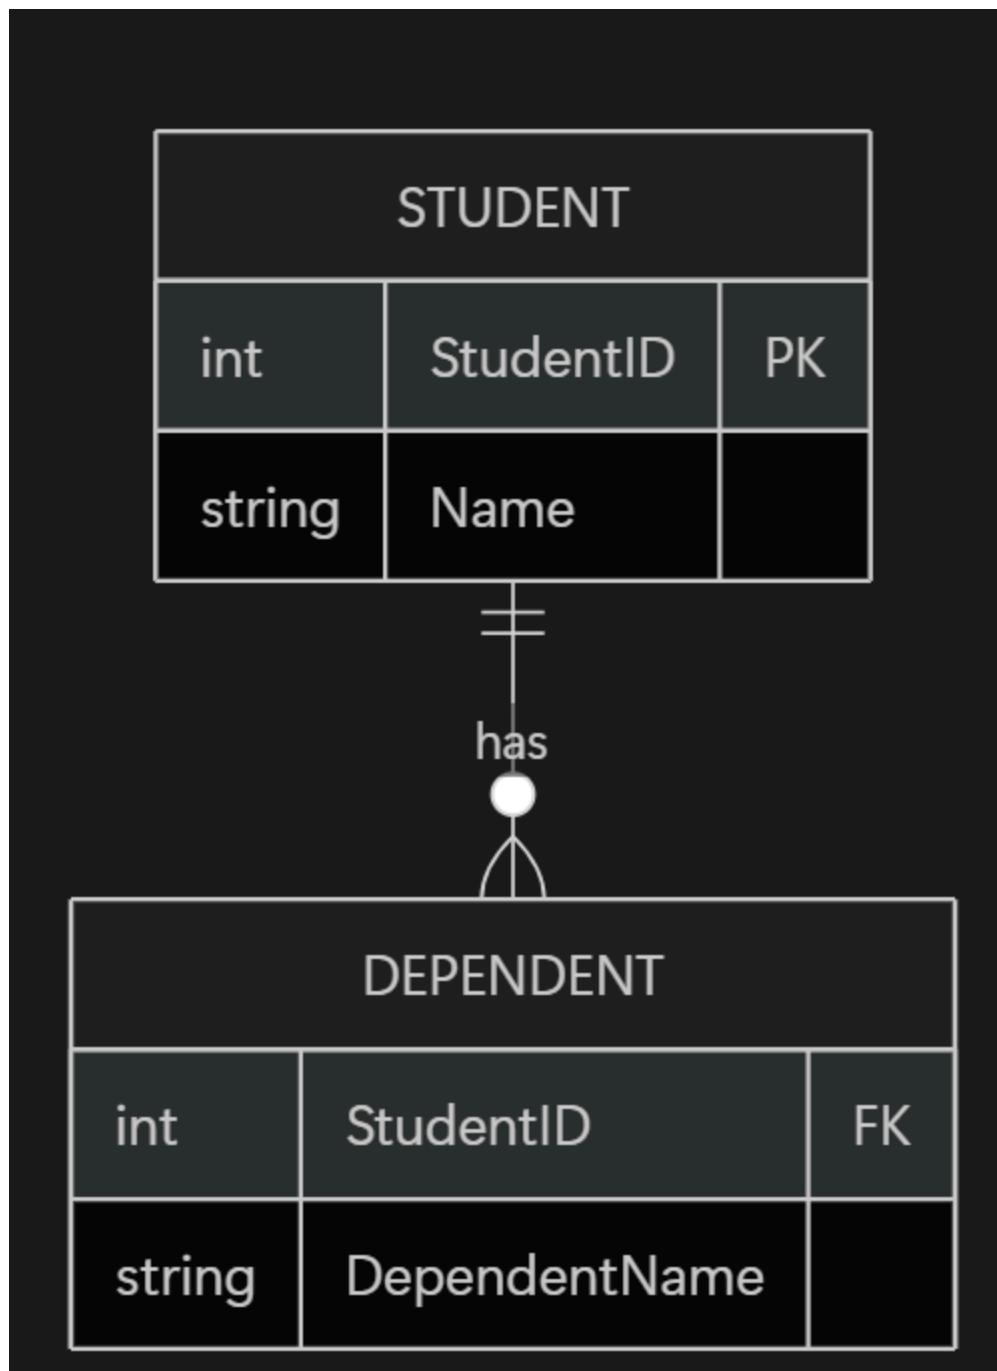

CUSTOMER(CustomerID PK, Name, Email, Phone)
PRODUCT(ProductID PK, ProductName, Price, StockQty)
ORDER(OrderID PK, OrderDate, CustomerID FK)
ORDER_DETAILS(OrderID FK, ProductID FK, Quantity)
PAYMENT(PaymentID PK, OrderID FK, Amount, Date, Mode)

```

4. Strong vs Weak Entity Sets

Feature	Strong Entity	Weak Entity
Existence	Independent	Depends on strong entity
Key	Has primary key	Has partial key
Example	STUDENT(StudentID, Name)	DEPENDENT(StudentID FK, DependentName)
Relationship	Identifying not needed	Needs identifying relationship

5. Functional Dependency (FD)

A **Functional Dependency** (FD) is a relationship between attributes such that one attribute uniquely determines another.

Example:

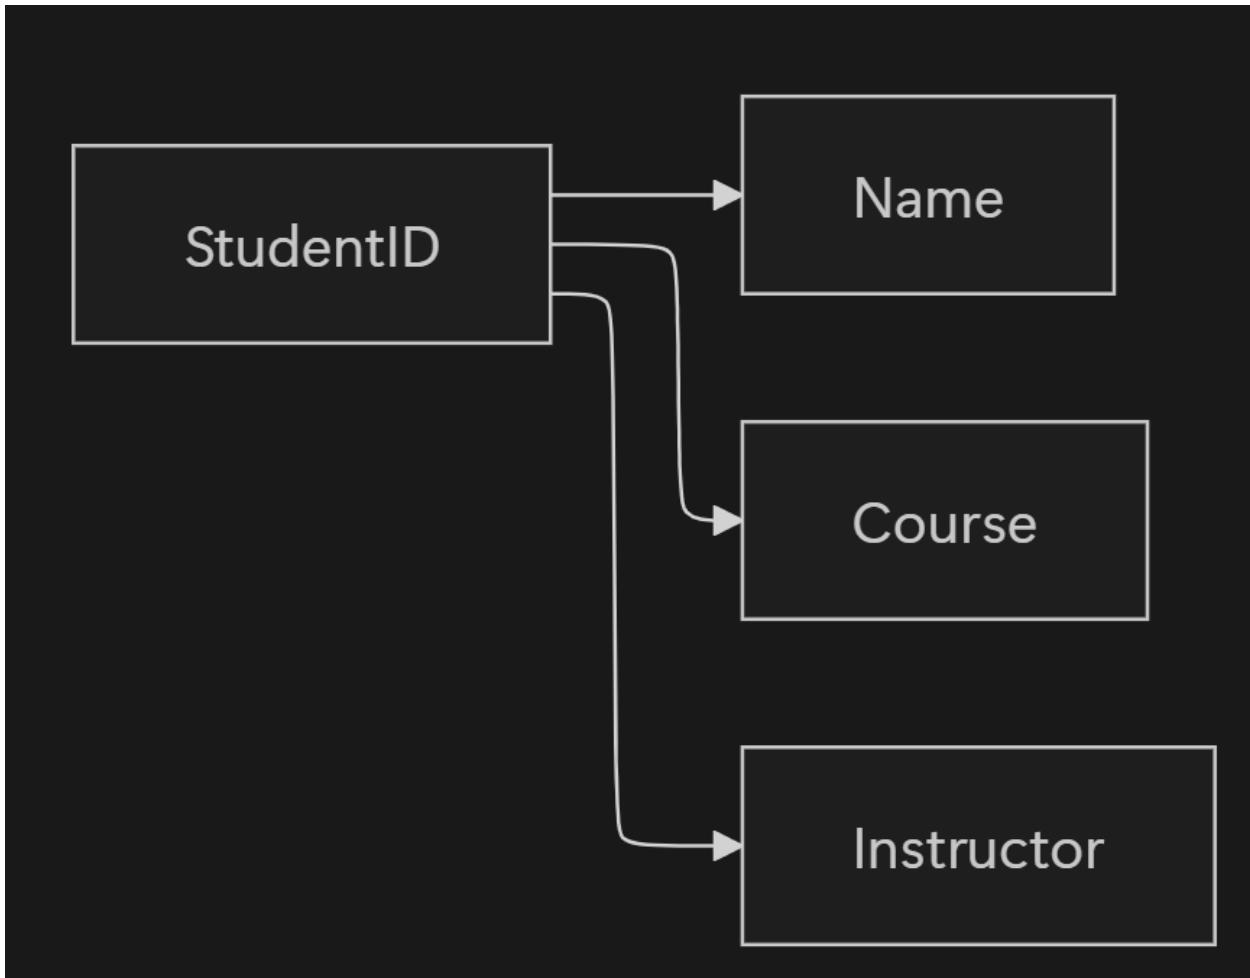

If $A \rightarrow B$, then for every value of A, there is exactly one value of B.

Candidate Key Identification Example:

STUDENT(StudentID, Name, Course, Instructor)

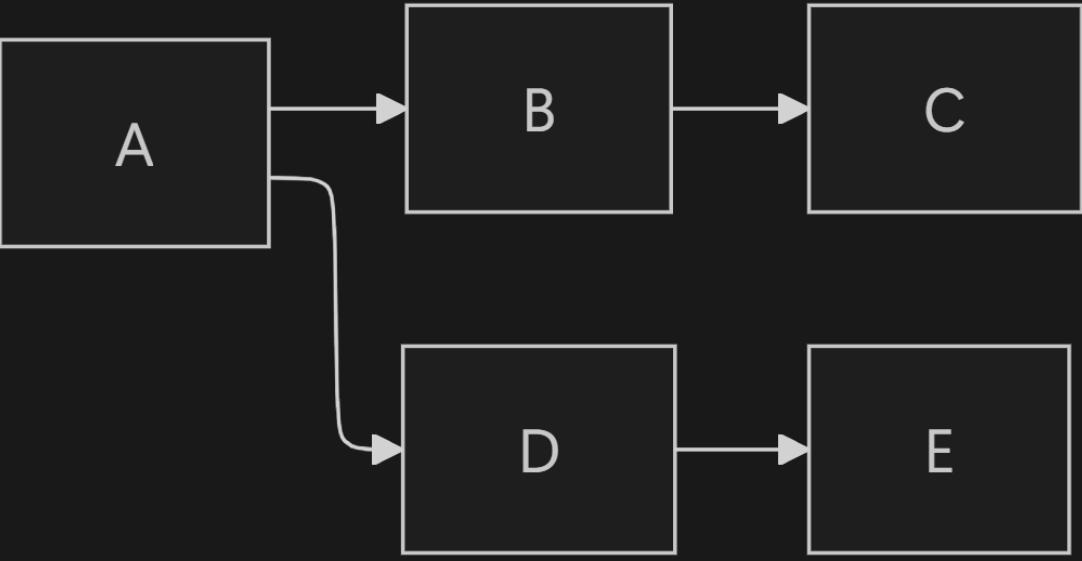

FDs: $\text{StudentID} \rightarrow \text{Name, Course, Instructor}$

Here, StudentID uniquely identifies all attributes \rightarrow Candidate Key = {StudentID}.

6. Relation R(A, B, C, D, E)

FDs: $\{A \rightarrow B, B \rightarrow C, A \rightarrow D, D \rightarrow E\}$

Step 1: Find Closure of A

$A^+ = \{A, B, C, D, E\} \rightarrow A$ is a **Candidate Key**.

Step 2: Normalize

- **1NF:** Already atomic.
- **2NF:** No partial dependency (A is single attribute key).
- **3NF:** Each non-prime attribute depends only on key.

Decomposition:

```

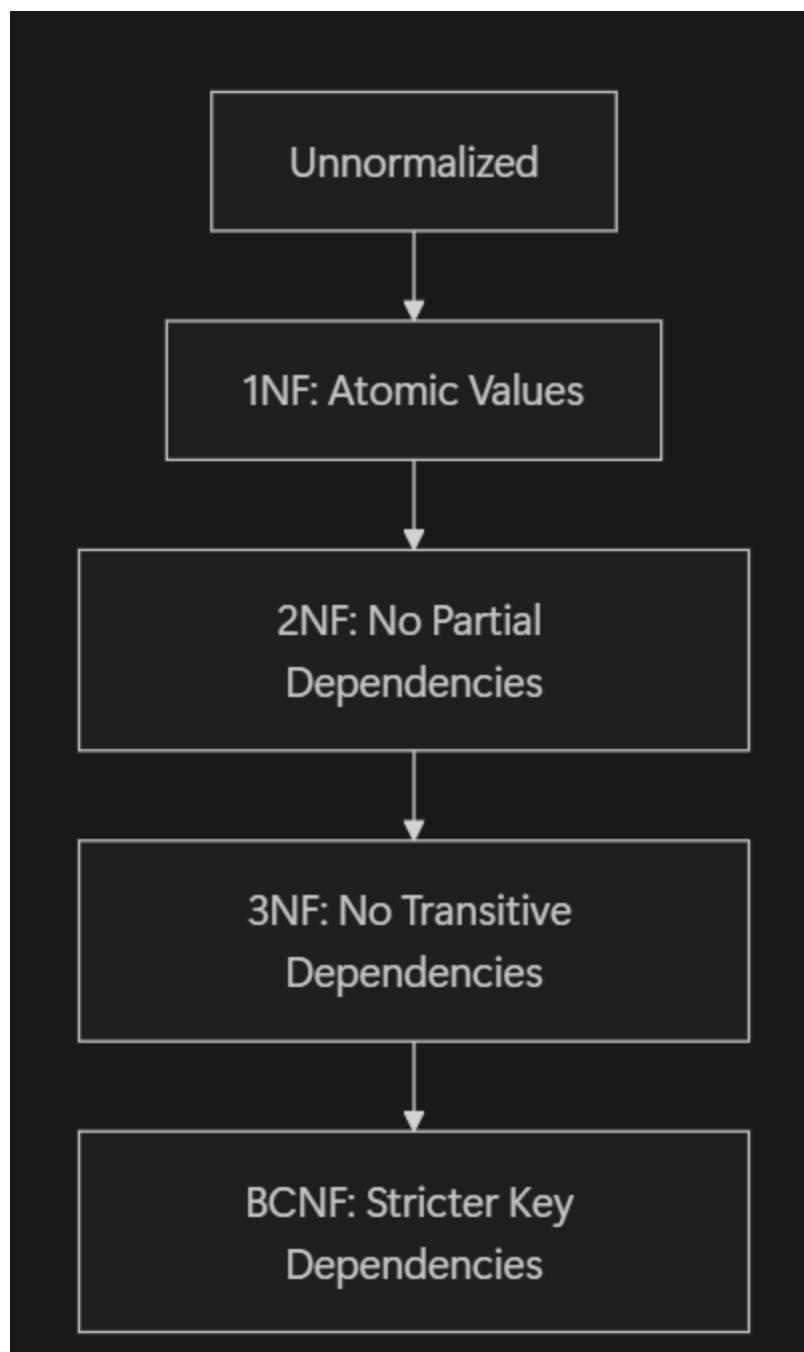

R1(A, B, C, D, E) →
R1(A, B, D)
R2(B, C)
R3(D, E)

```

7. 1NF, 2NF, 3NF Differences

Normal Form	Condition	Example
-------------	-----------	---------

1NF	No multivalued attributes.	StudentID, Subjects {Math, CS}
2NF	1NF + No partial dependency on part of composite key.	$(\text{RollNo}, \text{Subject}) \rightarrow \text{Marks}$
3NF	2NF + No transitive dependency.	$\text{RollNo} \rightarrow \text{Dept} \rightarrow \text{HOD}$

8. Relational Algebra

(a) Employees with salary > 50,000:

$\sigma_{\text{Salary} > 50000}(\text{EMPLOYEE})$

(b) Departments with >5 employees:

$\pi_{\text{DeptID}}(\sigma_{\text{COUNT}(\text{EmpID}) > 5}(\text{EMPLOYEE}))$

(Using aggregation equivalent).

9. Library Management System (ER + Schema)

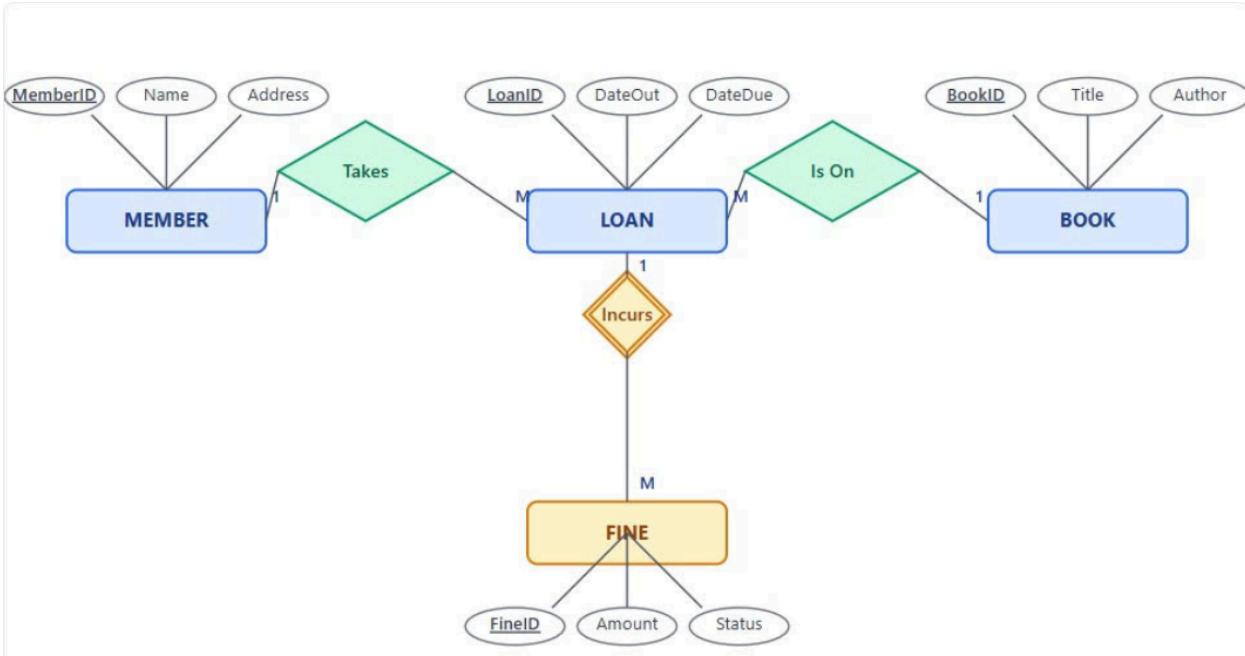

Entities:

- BOOK(BookID, Title, Author, Publisher)
- MEMBER(MemberID, Name, Address)
- LOAN(LoanID, BookID, MemberID, IssueDate, ReturnDate)
- FINE(FineID, LoanID, Amount, DatePaid)

Relationships:

- MEMBER borrows BOOK (via LOAN)
- LOAN may have FINE

ER Model:

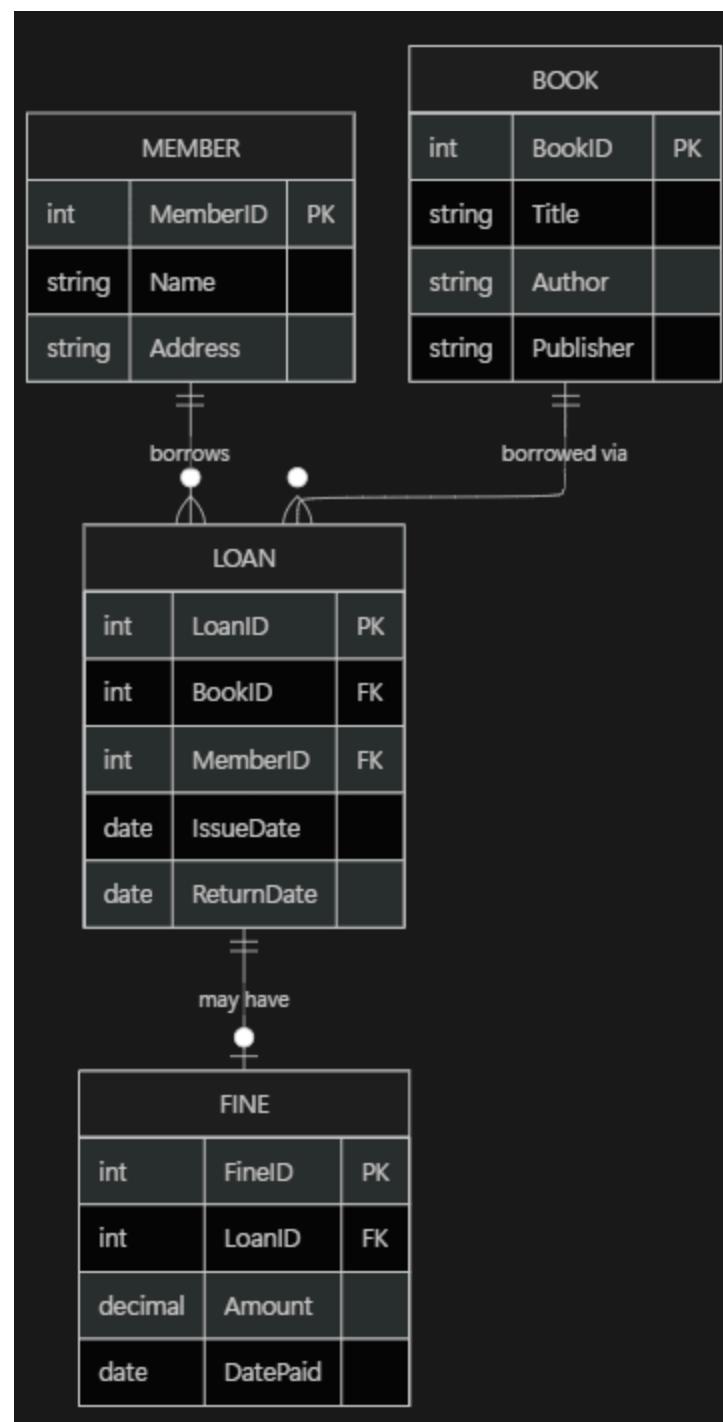

Schema:

BOOK(BookID PK, Title, Author, Publisher)

MEMBER(MemberID PK, Name, Address)

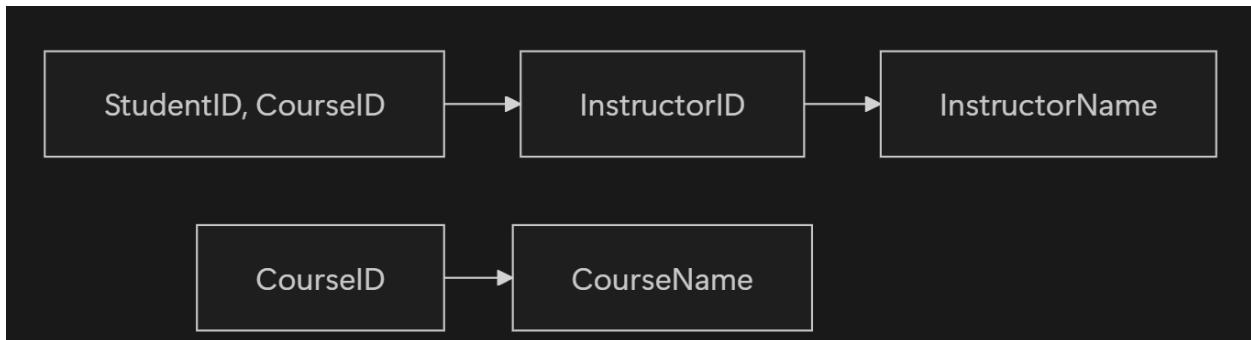

LOAN(LoanID PK, BookID FK, MemberID FK, IssueDate, ReturnDate)

FINE(FineID PK, LoanID FK, Amount, DatePaid)

10. Relation R(StudentID, CourseID, InstructorID, InstructorName, CourseName)

FDs: {StudentID, CourseID → InstructorID; InstructorID → InstructorName; CourseID → CourseName}

3NF Decomposition:

R1(StudentID, CourseID, InstructorID)

R2(InstructorID, InstructorName)

R3(CourseID, CourseName)

→ Each table now satisfies 3NF (no transitive dependencies).

11. Redundancy & Anomalies Reduction

Redundancy: Repetition of data (e.g., same InstructorName stored multiple times).

Anomalies:

- **Insertion:** Cannot insert course without student.
- **Updation:** Change in instructor name requires multiple updates.
- **Deletion:** Deleting last student may delete course info.

Normalization splits data into logical tables → removes these anomalies.

12. Relational Algebra Queries

Given:

EMPLOYEE(EmpID, Name, DeptID, Salary)
DEPARTMENT(DeptID, DeptName, Location)

(a) Average salary per department:

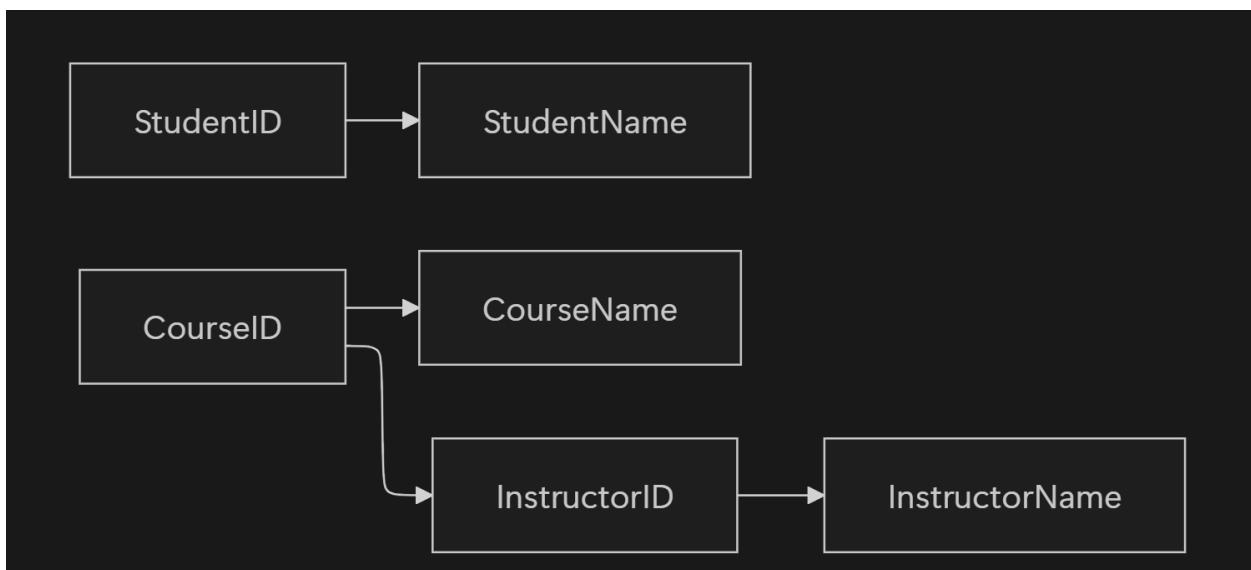

$\gamma_{\text{DeptID}} \text{ AVG}(\text{Salary})(\text{EMPLOYEE})$

(b) Names of employees in 'IT' dept:

$\pi_{\text{Name}}(\sigma_{\text{DeptName}='IT'}(\text{EMPLOYEE} \bowtie \text{EMPLOYEE}.\text{DeptID} = \text{DEPARTMENT}.\text{DeptID}))$
DEPARTMENT)

13. STUDENT_INFO Decomposition

FDs: {StudentID → StudentName, CourseID → CourseName, InstructorID → InstructorName, CourseID → InstructorID}

Anomalies:

- Redundant instructor and course names.
- Update anomalies.

Normalization:

1. **1NF:** Already atomic.
2. **2NF:** Key = (StudentID, CourseID). Split partial dependencies.

R1(StudentID, StudentName)
R2(CourseID, CourseName, InstructorID)

3. **3NF**: InstructorID → InstructorName → Separate table.

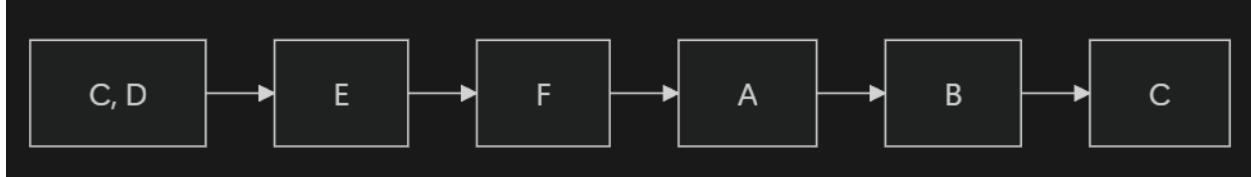

R3(InstructorID, InstructorName)

Final 3NF:

R1(StudentID, StudentName)
R2(CourseID, CourseName, InstructorID)
R3(InstructorID, InstructorName)

14. Relation R(A, B, C, D, E, F)

FDs: {A → B, B → C, CD → E, E → F, F → A}

Step 1: Closure

From F → A → B → C, CD → E → F forms a loop.

Candidate Key = {C, D}.

Step 2: Highest Normal Form

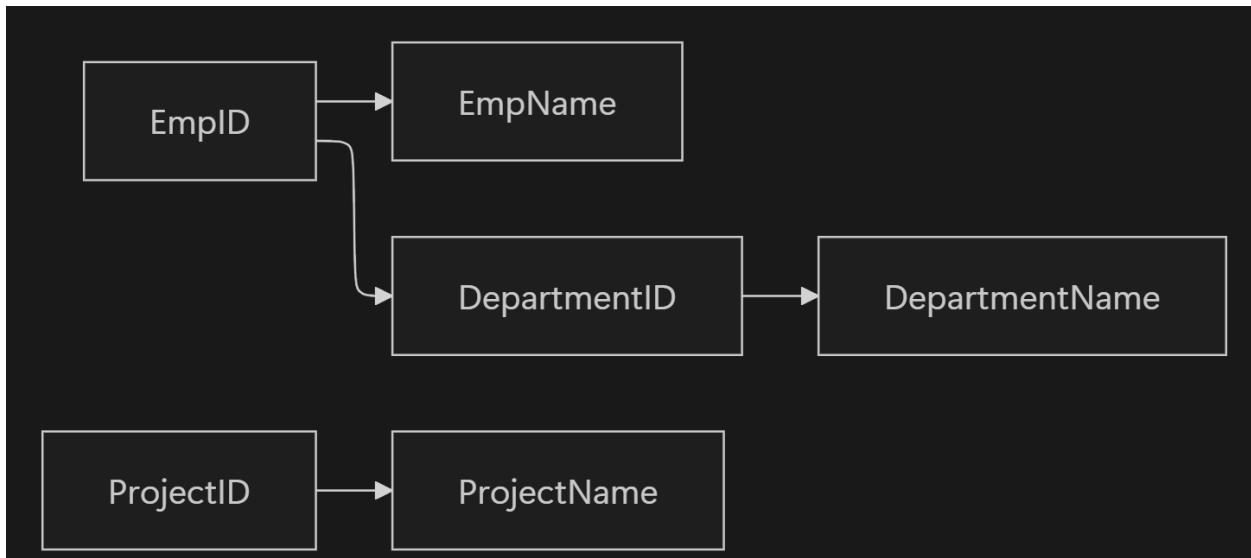

There are transitive dependencies → Not in 3NF → Normalize.

3NF Decomposition:

R1(A, B, C)
R2(C, D, E)
R3(E, F)

15. EMP_PROJECT(EmpID, EmpName, ProjectID, ProjectName, DepartmentID, DepartmentName)

FDs: {EmpID → EmpName, ProjectID → ProjectName, DepartmentID → DepartmentName, EmpID → DepartmentID}

Candidate Key: {EmpID, ProjectID}

Normalization:

1. **1NF:** Atomic.
2. **2NF:** Remove partial dependency on EmpID.

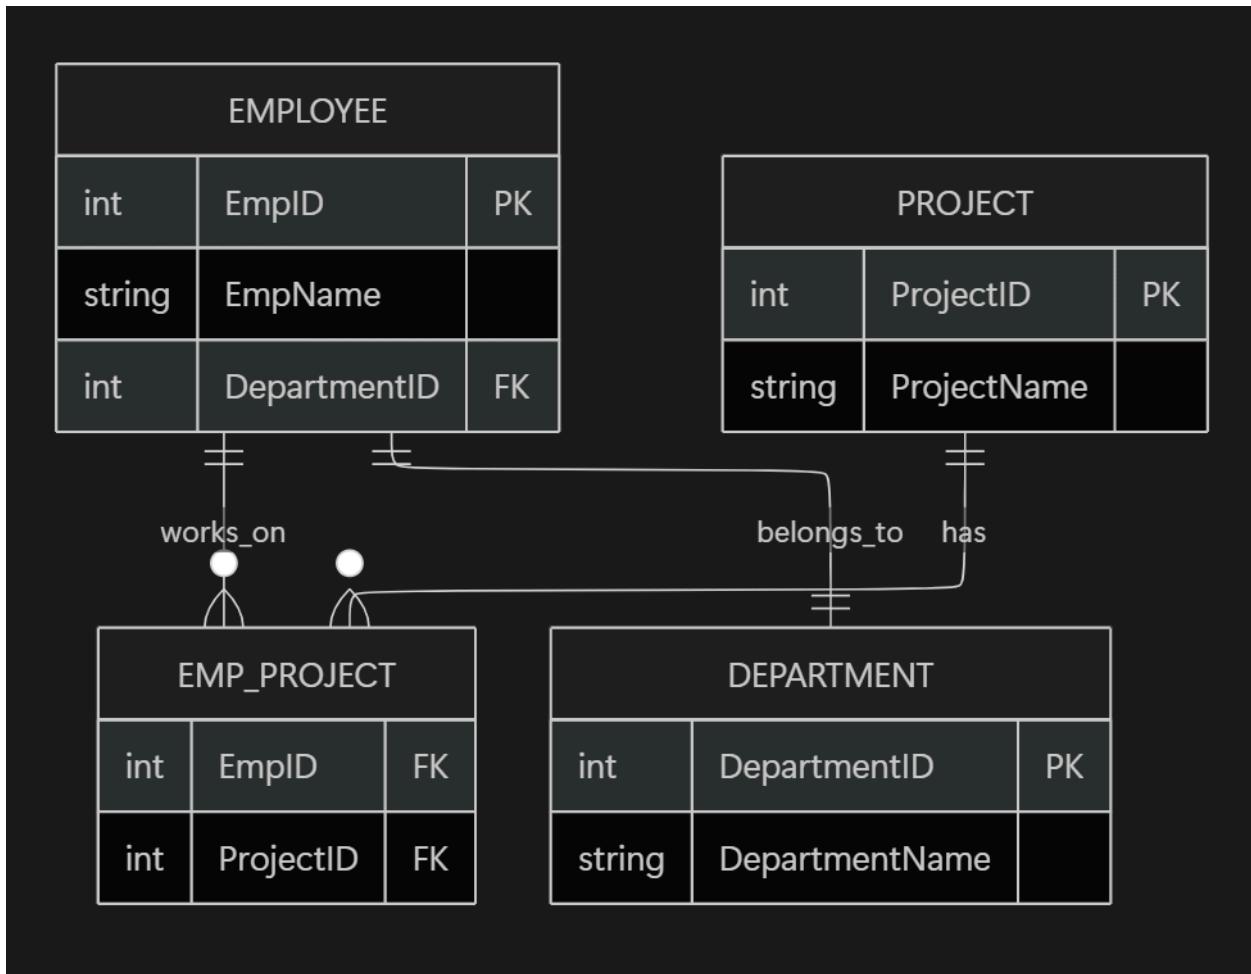

```
R1(EmpID, EmpName, DepartmentID)  
R2(ProjectID, ProjectName)
```

3. **3NF:** DepartmentID → DepartmentName ⇒ separate table.

```
R3(DepartmentID, DepartmentName)  
R4(EmpID, ProjectID)
```

Final 3NF:

R1(EmpID, EmpName, DepartmentID)
 R2(ProjectID, ProjectName)
 R3(DepartmentID, DepartmentName)
 R4(EmpID, ProjectID)

Normalization eliminates redundant department and project data.
